Microalbuminuria in patients with diabetes
What is Microalbuminuria?
Microalbuminuria means there is a small leak of protein (albumin) from the kidneys into the urine.

Why is it important in patients with diabetes?
It tells us who is at greater risk of developing kidney and heart disease in the future. It does not mean that your kidneys are not working properly now.

Why does Microalbuminuria occur?
The cause is unclear, but certain things increase the risk of developing microalbuminuria, they are:
• Smoking
• Badly controlled blood sugar levels
• Badly controlled blood pressure
• There is a higher risk in people who are South Asian or African-Caribbean

How is it detected?
It is detected by testing the sample of urine that you provide for your annual review with the doctor. Your doctor may ask you for further urine samples to confirm the results.

Who should be checked?
All patients with diabetes should be checked every year.

What happens if you have Microalbuminuria?
You will receive the same care as before but you will need to keep tight control of your blood sugar and blood pressure.

This has been shown to help slow down or stop the microalbuminuria. We will help you to achieve this.

We may offer treatment with a tablet ‘Angiotensin Converting Enzyme ACE inhibitor’ (e.g Lisinopril, Ramipril, Perindopril) or an Angiotensin two Receptor Antagonist (e.g. Valsartan, Irbesartan, Losartan).

These medicines have been shown to slow down or stop microalbuminuria. They also lower blood pressure and help the heart to work more efficiently.

Our aim is to work with you to try and reduce the protein leak from your kidneys by these measures and so reduce your risk of developing any kidney or heart problems

What can you do?
You can help look after your kidney and heart by:
• Stopping smoking.
• Improving the control of your blood sugar, by checking your sugar levels with urine or blood tests - this tells you how well you are doing and gives us a lot of information when we see you at the clinic.
• Controlling your blood pressure by taking your tablets regularly (if you need to have them).
• Cutting down the salt in your meals.
• Taking regular exercise which will help your heart and keep your blood sugar and blood pressure lower.

What is the long term outlook?
By good control of your diabetes and making lifestyle changes, you can help prevent the Microalbuminuria causing kidney and heart problems.
